

# Two Column Note-taking Method

Topic: Factoring by Grouping  
Section: 3.5; pg. 426 - 430

Include Topic, section and page numbers.

Date: 9/23/2015

Include the date you took the notes.

Concepts/Procedures/Main Ideas

Examples

Right column is for examples

Left column is for concepts, procedures

## Factoring by Grouping:

- used for 4-term polynomials OR for 3-term polynomials when the coefficient of the leading term is bigger than 1

### Procedure:

- Factor out the GCF, if there is one from all four terms.
- If necessary, rearrange the terms so that the first two terms have a common factor and the last two terms have a common factor.
- Then, use the distributive property to factor each group of two terms.

Use color to highlight certain points or to bring attention to important test information on which you might be tested.

- Factor the GCF from the results of step 3.

Leave enough white space in your notes so you can add clarifying information.

### Caution!

- Don't forget to include any GCF that you factored out in step 1 in your final answer!
- If the first term of the second group is a negative number, factor out the negative GCF! (like in this example)

Example 1: Factor the following 4-term polynomial:

$$x^2y + 2xy - 6xy - 12y$$

- GCF is  $y$ , so factor it out:  $y(x^2 + 2x - 6x - 12)$
- Didn't have to rearrange the terms in this example, so go to step 3.

- $y[x(x+2) - 6(x+2)]$   
**Note:** use brackets around the polynomial inside the parentheses so that you don't lose track of the GCF! It's part of the final answer!

- The GCF of the two terms inside the brackets is a binomial,  $(x + 2)$  so factor it out now.

$$y[(x+2)(x-6)]$$

**Careful!** Always make sure that your final factorization is completely factored!

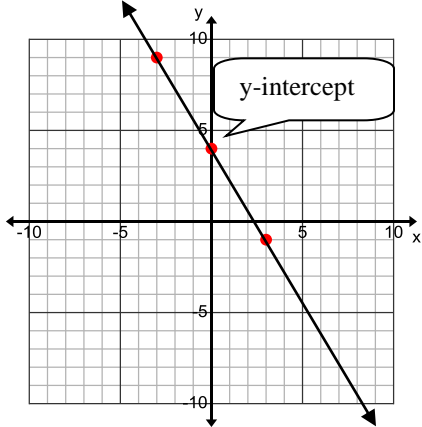

Include any written explanations or diagrams/pictures that help you understand the problems. Write out explanations in your own words.

At the end of each page, leave room for a place to write questions you may have for your instructor or tutor.

## Questions/Clarification:

- Do I have to use brackets?
- Is it the same if I write the answer with factors in a different order?
- Can I use this method for any of my factoring problems?

## Three Column Note-taking Method

<p><b>Topic:</b> How to graph a linear equation using the slope-intercept method</p>	<p><b>Section:</b> 6.2</p>	<p><b>Date:</b> 10/15/2015</p>
<p><b>Key Words/Rules</b></p>	<p><b>Examples</b></p>	<p><b>Explanations/Procedures</b></p>
<p>Slope-Intercept Method for graphing linear equations:</p>	<p>Graph <math>5x + 3y = 12</math> by using the slope and y-intercept.</p> $3y = -5x + 12$ $\frac{3y}{3} = \frac{-5x}{3} + \frac{12}{3}$ $y = \frac{-5x}{3} + 4$  <p>The slope is <math>-\frac{5}{3}</math>. So, from the y-intercept, we will move down 5 units from the intercept and then to the right 3 units to find another point on the line.</p> <p>We can also move 5 units up from the intercept and down 3 units to find another point on the line.</p>	<ol style="list-style-type: none"> <li>If necessary, solve the equation for y. (<math>y = mx + b</math>)</li> </ol> <p><b>Caution!</b> Don't forget to divide all terms in the equation when solving the equation for y!</p> <ol style="list-style-type: none"> <li>Plot the y-intercept.</li> <li>Use the slope to find to find two or more points on the line.</li> <li>Using a straight-edge, draw a straight line through the three points. Draw an arrowhead on each end of the line.</li> </ol> <p><b>Note:</b> You Have not graphed the line until you draw a line through the points!!!</p>
<p style="text-align: center;"><b>Questions/Clarification</b></p> <p><b>Q1:</b> Why do I have to put arrows on the line?</p> <p><b>Q2:</b> What if I have a fraction for the y-intercept, then what do I do?</p>
